## - Linear Factor Models

### - About Linear Factor Model

- The simplest probabilistic models with latent variables
- Defined by the use of stochastic linear decoder function;  $\mathbf{x} = \mathbf{W}\mathbf{h} + \mathbf{b} + \epsilon$
- Data generation process
  - Sample  $\mathbf{h}$  from dist.  $\mathbf{h} \sim p(\mathbf{h})$  s.t.  $p(\mathbf{h}) = \prod_i p(h_i)$
  - Sample  $\mathbf{x}$  based on given factors;  $\mathbf{x} = \mathbf{W}\mathbf{h} + \mathbf{b} + \epsilon$
  - Noise  $\epsilon$  is typically Gaussian & diagonal; indep. across dimensions.
- Illustration :

# PPCA & FA

- Outlines & about FA

- Probabilistic PCA & FA, etc. are special cases of prev. slide
  - Difference : Choosing dist. of noise  $\epsilon$  and prior of  $\mathbf{h}$  before observing  $\mathbf{x}$
- FA : prior of latent variable  $\mathbf{h}$  is just; Gaussian  $\mathbf{h} \sim \mathcal{N}(\mathbf{h}; \mathbf{0}, \mathbf{I})$ 
  - Given  $\mathbf{h}$ , observed  $x_i$ s are assumed to be conditionally indep.
- Noise  $\epsilon$  is assumed to be;  $\epsilon \sim \mathcal{N}(\epsilon; \mathbf{0}, \Psi)$ , s.t.  $\Psi = \text{diag}(\sigma^2)$  &  $\sigma^2 = [\sigma_i^2]^T$
- The role of latent variables : *'capture the dependencies'* b/w the different observed  $\mathbf{x}$ , it's easy to see that  $\mathbf{x} \sim \mathcal{N}(\mathbf{x}; \mathbf{b}, \mathbf{W}\mathbf{W}^T + \Psi)$

# PPCA & FA

- About Probabilistic PCA

- PCA in a 'Probabilistic' framework; modify to FA model
  - Set  $\sigma_i^2 = \sigma^2$  for  $\forall i = 1, 2, \dots, n$ ; so that  $\mathbf{x} \sim \mathcal{N}(\mathbf{x}; \mathbf{b}, \mathbf{W}\mathbf{W}^T + \sigma^2\mathbf{I})$
  - Equivalently,  $\mathbf{x} = \mathbf{W}\mathbf{h} + \mathbf{b} + \sigma\epsilon$  s.t.  $\epsilon \sim \mathcal{N}(\epsilon; \mathbf{0}, \mathbf{I})$
  - By iterative EM algorithm, we can estimate  $\mathbf{W}$  &  $\sigma^2$
- Based on the observation that most variations in the data can be captured by  $\mathbf{h}$ , up to some small residual reconstruction error
- As  $\sigma \rightarrow 0$ , then  $\mathbf{x} = \mathbf{W}\mathbf{h} + \mathbf{b} + \sigma\epsilon \xrightarrow{p} \mathbf{x} = \mathbf{W}\mathbf{h} + \mathbf{b}$  (PPCA  $\xrightarrow{p}$  PCA)

# ICA

- About Independent Component Analysis

- Forming observed data by separating observed signal into many underlying signals that are scaled & added together
- An approach to modeling linear factors
  - Signals are intended to be not only uncorrelated from each other, but also fully independent.
- There exists many variances referred to as ICA
- Introduced variant: training fully parametric model
  - Prior of the underlying factors,  $p(\mathbf{h})$ , must be fixed in advance.
  - Then the model generates  $\mathbf{x} = \mathbf{W}\mathbf{h}$ , determine  $p(\mathbf{x})$  by transformation
  - And learning model using maximum likelihood

# ICA

- Motivation of 'The' Variant/some examples

- By choosing  $p(\mathbf{h})$  to be independent, we can recover underlying factors as close as possible to be independent
- Commonly used to recover mixed low-level signals
- Ex) commonly used in neuroscience, for the electro-encephalography
  - To separate signals of the heart from signals of the brain
  - And to separate signals in different regions of the brain from each other

Then the volume of parallelepiped is;  $|D(\mathbf{a}, \mathbf{b}, \mathbf{c})| = \text{abs} \begin{vmatrix} \beta_1 - \alpha_1 & \beta_2 - \alpha_2 & \beta_3 - \alpha_3 \\ \gamma_1 - \alpha_1 & \gamma_2 - \alpha_2 & \gamma_3 - \alpha_3 \\ \delta_1 - \alpha_1 & \delta_2 - \alpha_2 & \delta_3 - \alpha_3 \end{vmatrix}$

Obviously, our desired volume of tetrahedron is  $\frac{1}{6} |D(\mathbf{a}, \mathbf{b}, \mathbf{c})|$ .

# ICA

- Non-Gaussian prior requirement

- All variants have common requirement: non-Gaussian prior  $p(\mathbf{h})$ 
  - We cannot identify  $\mathbf{W}$  if  $p(\mathbf{h}) \sim \text{Gaussian Normal}$
  - In other words, we can obtain same  $p(\mathbf{x})$  for many  $\mathbf{W}$
- Quite different from other LFMs such as PPCA, FA which require Gaussian prior  $p(\mathbf{h})$  to make operations have closed solutions
- For 'the' variant, we typically use  $p(h_i) = \frac{d}{dh_i} \sigma(h_i) = \frac{d}{dh_i} \left( \frac{1}{1+e^{-h_i}} \right)$
- Have larger peaks near 0 than Gaussian
- So most ICA implementations aim at learning sparse features

# ICA

- Another Variants

- There's a variant that adds some noise in the generation of  $\mathbf{x}$  rather than deterministic decoder
- It aims to make the elements of  $\mathbf{h} = \mathbf{W}^{-1}\mathbf{x}$  independent from each other
- Some variants constrains  $\mathbf{W}$  to be orthogonal to avoid possibly problematic operation determinant
- Some variants is not a 'generative model'
  - Many variants only know transformation b/w  $\mathbf{x}$  &  $\mathbf{h}$ , but do not have any way of representing  $p(\mathbf{h})$  so it does not impose distribution over  $p(\mathbf{x})$
  - Ex) many variants aim to increase sample kurtosis of  $\mathbf{h} = \mathbf{W}^{-1}\mathbf{x}$

# ICA

- Generalizations : NICE/ISA/Topographic ICA

- NICE(Non-linear Independent Components Estimation)

- ISA(Independent Subspace Analysis)

- Topographic ICA

# SFA

- About Slow Feature Analysis

- LFM that uses information from time signals to learn invariant features
- Based on the Slowness principle
  - Idea : important characteristics of scenes change very slowly
  - Can be applied to any differentiable model trained with GD generally
  - By adding a term to cost function of the form  $\lambda \sum_t L(f(\mathbf{x}^{(t+1)}), f(\mathbf{x}^{(t)}))$  to apply the Slowness principle
- Efficient application of the slowness principle; because it is applied to a linear feature extractor

# SFA

- SFA Algorithm

- Defining  $f(\mathbf{x}; \boldsymbol{\theta})$  as a linear transformation

- And solve;  $\min_{\boldsymbol{\theta}} \mathbb{E}_t \left[ \left( f(\mathbf{x}^{(t+1)})_i - f(\mathbf{x}^{(t)})_i \right)^2 \right]$ ,

- With constraints;  $\mathbb{E}_t f(\mathbf{x}^{(t)})_i = 0$  &  $\mathbb{E}_t \left[ \left( f(\mathbf{x}^{(t)})_i \right)^2 \right] = 1$

- 1st constraint : to obtain a unique solution

- 2nd constraint : to prevent solution where all features collapse to 0

- SFA features are ordered like PCA

- The first feature is the slowest one

# SFA

- SFA Algorithm/Generalizations/Advantages

- Additional constraint to learn multiple features;

$$\mathbb{E}_t \left[ f(\mathbf{x}^{(t)})_i f(\mathbf{x}^{(t)})_j \right] = 0 \text{ for any } i < j$$

- So the learned features must be linearly uncorrelated from each other

- Typically used to learn non-linear features by applying nonlinear expansion to input signals before running it

- Major advantage : possible to theoretically predict which features SFA will learn

- Even in the deep nonlinear setting

# Sparse Coding

- Training Sparse Coding model

- Encoder of the SC model is kind of optimization algorithm;
  - Solving  $\mathbf{h}^* = \operatorname{argmax}_{\mathbf{h}} p(\mathbf{h}|\mathbf{x}) = \operatorname{argmin}_{\mathbf{h}} \lambda \|\mathbf{h}\|_1 + \beta \|\mathbf{x} - \mathbf{W}\mathbf{h}\|_2^2$
  - This yields a sparse  $\mathbf{h}^*$  because of the L1 norm imposition on  $\mathbf{h}$
- To train model, we alternate b/w minimization wrt  $\mathbf{h}$  and  $\mathbf{W}$ 
  - We treat  $\beta$  as a hyper-parameter; we typically set it to 1 because it's role is shared with  $\lambda$  in opt. problem
  - If we want to learn  $\beta$ , we must consider discarded terms

# Sparse Coding

## - Advantages

- Sparse Coding + non-parametric encoder
  - Can minimize the (reconstruction error + log-prior) better than any specific parametric encoder in principle
  - There's no generalization error; so applying sparse coding to feature extractor for a classifier makes better generalization than applying it as parametric func. to predict the code

# Sparse Coding

## - Disadvantages

- non-parametric encoder
  - The primary disadvantage : large time cost of calculating  $(\mathbf{h}|\mathbf{x})$  because of iterative algorithm of non-parametric approach
  - Not easy to use back-prop. through the non-parametric encoder
- Often produces poor samples like other LFMs
- Motivated the development of improved models
