Distributions for Categorical Data

Binomial/Multinomial Distribution

- Bernoulli trials $\{Y_i\}$: independent and identical

$$P(Y_i = 1) = \pi \quad P(Y_i = 0) = 1 - \pi$$

- The total number of successes, $Y = \sum_{i=1}^n Y_i \sim \text{bin}(n, \pi)$

$$P(Y = y) = \binom{n}{y} \pi^y (1 - \pi)^{n-y}$$

$$Y \approx \mathcal{N}(n\pi, n\pi(1 - \pi))$$

- Multinomial Distribution :

$$P(n_1, n_2, \dots, n_{c-1}) = \frac{n!}{n_1! n_2! \dots n_{c-1}!} \pi_1^{n_1} \pi_2^{n_2} \dots \pi_c^{n_c}$$

Distributions for Categorical Data

Poisson Distribution

It is used for counts of events that occur randomly over time or space.

- The Poisson postulates :
 $g(x, w)$: probability of x changes in each interval of length w .
 - 1 $g(1, h) = \lambda h + o(h)$, λ : positive constant, $h > 0$
 - 2 $\sum_{x=2}^{\infty} g(x, h) = o(h)$
 - 3 The number of changes in nonoverlapping intervals are independent
- $g(x, w) = \frac{e^{-\lambda w} (\lambda w)^x}{x!}$, $x = 0, 1, 2, \dots$
- $Y \approx \mathcal{N}(\mu, \sqrt{\mu^2})$ as $\mu \rightarrow \infty$
- $Y \approx \text{bin}(n, \pi)$ if n is large and π is small.

- 4 Statistical Inference for Multinomial Parameters

Distributions for Categorical Data

Overdispersion

Overdispersion is the presence of greater variability in a data set than would be expected based on a given statistical model.

(\because Poisson distribution is too simple.)

The probability of dying in fatal accident in the next week may vary due to many factors.

$$Y|\mu \sim \text{Poisson}(\mu), \quad \mathbb{E}\mu = \theta$$

$$\mathbb{E}(Y) = \mathbb{E}[\mathbb{E}(Y|\mu)], \quad \text{Var}(Y) = \mathbb{E}(\text{Var}(Y|\mu)) + \text{Var}(\mathbb{E}(Y|\mu))$$

$$\Rightarrow \mathbb{E}(Y) = \theta, \quad \text{Var}(Y) = \theta + \text{Var}(\mu) > \theta$$

In chapter 4, 12, and 13, the book introduces methods for data that are dispersed.

Distributions for Categorical Data

Connection between Poisson and Multinomial Distributions

Assume that Y_1, Y_2, \dots, Y_c are independent Poisson distributions with parameters μ_1, \dots, μ_c . Then, the total $n = Y_1 + \dots + Y_c$ also has Poisson distribution.

If we assume a Poisson model but condition on n , $\{Y_i\}$ no longer have Poisson distribution.

$$\begin{aligned} P(Y_1 = n_1, \dots, Y_c = n_c | \sum Y_j = n) &= \frac{P(Y_1 = n_1, \dots, Y_c = n_c)}{P(\sum Y_j = n)} \\ &= \frac{\prod_i \exp(-\mu_i) \mu_i^{n_i} / n_i!}{\exp(-\sum \mu_j) (\sum \mu_j)^n / n!} \\ &= \frac{n!}{\prod_i n_i!} \prod_i \pi_i^{n_i} \end{aligned}$$

Statistical Inference for Categorical Data

Likelihood Functions and Maximum Likelihood Estimation

$\hat{\beta} = \arg \max_{\beta} l(\beta) = \arg \max_{\beta} L(\beta)$ is called MLE.

- Likelihood equation :

$$\frac{\partial L(\beta)}{\partial \beta} = 0$$

- $cov(\hat{\beta})$ denote the asymptotic covariance of $\hat{\beta}$.

$$cov(\hat{\beta})^{-1/2}(\hat{\beta} - \beta) \xrightarrow{d} \mathcal{N}(0, I_k) \text{ as } n \rightarrow \infty$$

- SE denote the standard error of $\hat{\beta}$.
- Under regularity conditions, MLE is asymptotically efficient, i.e.,

$$\begin{aligned} cov(\hat{\beta}) &= \mathcal{I}_n(\beta)^{-1} = \mathbb{E} \left[\left(\frac{\partial L(\beta)}{\partial \beta} \right)^2 \right]^{-1} \\ &= -\mathbb{E} \left(\frac{\partial^2 L(\beta)}{\partial \beta \partial \beta^T} \right)^{-1} \end{aligned}$$

Statistical Inference for Categorical Data

Hypothesis Testing

Situation : $H_0 : \beta = \beta_0$, realization of MLE is $\hat{\beta}$

Reject or Not??

Statistical Inference for Categorical Data

Hypothesis Testing : Likelihood Ratio Test

Theorem (Likelihood Ratio Test)

For testing $H_0 : \beta = \beta_0$ versus $H_1 : \beta \neq \beta_0$, suppose X_1, \dots, X_n are iid $f(x|\beta)$, $\hat{\beta}$ is the MLE of β , and $f(x|\beta)$ satisfies the regularity conditions. Then under H_0 , as $n \rightarrow \infty$,

$$-2 \log \Lambda(X) \xrightarrow{d} \chi_1^2$$

where $\Lambda(X) = \frac{l(\beta_0)}{l(\hat{\beta})}$.

We would reject H_0 at level α if $-2 \log \Lambda(x) > \chi_{1,\alpha}^2$

Lemma (Asymptotic efficiency)

Let $\hat{\beta}$ is the MLE of β , and $\tau(\beta)$ be a continuous function of β . Under the regularity conditions, $\tau(\hat{\beta})$ is a consistent and asymptotically efficient estimator of $\tau(\theta)$.

Statistical Inference for Categorical Data

Hypothesis Testing : Likelihood Ratio Test

Theorem (Likelihood Ratio Test)

Under the same condition,

$$-2 \log \Lambda(X) \xrightarrow{d} \chi^2_\nu$$

where $\Lambda(X) = \frac{\sup_{\Theta_0} l(\beta)}{\sup_{\Theta_0 \cup \Theta_1} l(\beta)}$ and $\nu = \dim(\Theta_0 \cup \Theta_1) - \dim(\Theta_0)$.

proof on Shao's book Thm 6.5

Statistical Inference for Categorical Data

Hypothesis Testing : Wald Test

Use the large-sample normality of MLE, i.e.,

$$z_n = \frac{\hat{\beta} - \beta_0}{SE} \xrightarrow{d} \mathcal{N}(0, I_k)$$

We would reject H_0 if and only if $z_n < -z_{\alpha/2}$ or $z_n > z_{\alpha/2}$

Example(Large sample binomial test)

Let $X_1, \dots, X_n \stackrel{iid}{\sim} \text{Bernoulli}(p)$. Consider testing $H_0 : p \leq p_0$ versus $H_1 : p > p_0$. The Wald test statistic $z_n = ?$

Statistical Inference for Categorical Data

Hypothesis Testing : Score Test

The score function is defined to be

$$u(\beta) = \partial L(\beta) / \partial \beta, \quad \mathbb{E}u(\beta) = 0, \quad \text{Var}(u(\beta)) = \mathcal{I}_n(\beta)$$

By Central Limit Theorem,

$$u(\beta) / \sqrt{\mathcal{I}_n(\beta)} \xrightarrow{d} \mathcal{N}(0, I_k)$$

The score statistic $Z_S = u(\beta_0) / \sqrt{\mathcal{I}_n(\beta_0)}$

As $n \rightarrow \infty$, the Wald, likelihood-ratio, and score tests have certain asymptotic equivalences.

- 4 Statistical Inference for Multinomial Parameters

Statistical Inference for Binomial Parameters

Tests about a Binomial Parameter

ML estimator of π is $\hat{\pi} = y/n$.

- Wald statistic :

$$z_W = \frac{\hat{\pi} - \pi_0}{SE} \approx \frac{\hat{\pi} - \pi_0}{\sqrt{\hat{\pi}(1 - \hat{\pi})/n}}$$

- Score statistic :

$$z_S = \frac{u(\hat{\pi})}{\sqrt{\mathcal{I}_n(\hat{\pi})}} \approx \frac{u(\pi_0)}{\sqrt{\mathcal{I}_n(\pi_0)}} = \frac{\hat{\pi} - \pi_0}{\sqrt{\pi_0(1 - \pi_0)/n}}$$

- Likelihood Ratio :

$$\begin{aligned} -2(L_0 - L_1) &= 2 \left(y \log \frac{\hat{\pi}}{\pi_0} + (n - y) \log \frac{1 - \hat{\pi}}{1 - \pi_0} \right) \\ &= 2 \left(y \log \frac{y}{n\pi_0} + (n - y) \log \frac{n - y}{n - n\pi_0} \right) \end{aligned}$$

Statistical Inference for Binomial Parameters

Confidence Intervals for a Binomial Parameter

Wald test statistic gives the interval of π_0 values for which

$$\hat{\pi} \pm z_{\alpha/2} \sqrt{\frac{\hat{\pi}(1 - \hat{\pi})}{n}}$$

It performs poorly unless n is very large.

FIG. 1. Standard interval; oscillation phenomenon for fixed $p = 0.2$ and variable $n = 25$ to 100.

Statistical Inference for Binomial Parameters

Brown et al. 2001

FIG. 4. Coverage of the nominal 99% standard interval for fixed $n = 20$ and variable p .

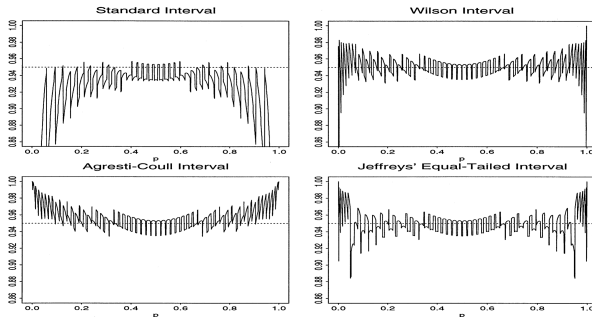

FIG. 5. Coverage probability for $n = 50$.

Statistical Inference for Binomial Parameters

Confidence Intervals for a Binomial Parameter

Score confidence interval : $|z_S| < z_{\alpha/2}$

Its endpoints are the π_0 solutions to the equations

$$(\hat{\pi} - \pi_0) / \sqrt{\pi_0(1 - \pi_0)/n} = \pm z_{\alpha/2}$$

$$\left(\frac{\hat{\pi} - \pi_0}{\sqrt{\pi_0(1 - \pi_0)/n}} \right)^2 = z_{\alpha/2}^2$$

$$\Leftrightarrow (n + z_{\alpha/2}^2)\pi_0^2 - (2n\hat{\pi} + z_{\alpha/2}^2)\pi_0 + n\hat{\pi}^2 = 0$$

$$\Leftrightarrow \pi_0 = \frac{(2n\hat{\pi} + z_{\alpha/2}^2) \pm \sqrt{(2n\hat{\pi} + z_{\alpha/2}^2)^2 - 4(n + z_{\alpha/2}^2)n\hat{\pi}^2}}{2(n + z_{\alpha/2}^2)}$$

Statistical Inference for Binomial Parameters

Confidence Intervals for a Binomial Parameter

$$\Leftrightarrow \pi_0 = \hat{\pi} \left(\frac{n}{n + z_{\alpha/2}^2} \right) + \frac{1}{2} \left(\frac{z_{\alpha/2}^2}{n + z_{\alpha/2}^2} \right) \pm z_{\alpha/2} \sqrt{\frac{1}{n + z_{\alpha/2}^2} \left[\hat{\pi}(1 - \hat{\pi}) \frac{n}{n + z_{\alpha/2}^2} + \frac{1}{2} \frac{z_{\alpha/2}^2}{n + z_{\alpha/2}^2} \right]}$$

The midpoint $\tilde{\pi}$ is a weighted average of $\hat{\pi}$ and $1/2$. And, the square of the coefficient of $z_{\alpha/2}$ is a weighted average of the variance.

- 4 Statistical Inference for Multinomial Parameters

Statistical Inference for Binomial Parameters

Proportion of Vegetarians Example

One question asked each student whether he or she was a vegetarian.
Of $n = 25$ students, $y = 0$ answered “yes”

The 95% interval for π is

- Wald : $0 \pm 1.96\sqrt{0.0 \times 1.0/25} = (0, 0)$
- LRT : $-2 \log \Lambda(x) = -50 \log(1 - \pi_0) \leq \chi_{1,0.05}^2 = (0, 0.074)$
- Score : $(0.0, 0.133)$, more believable inference

For $H_0 : \pi = 0.5$, the score test statistic is

$$z_S = (0 - 0.5) / \sqrt{0.5 \times 0.5 / 25} = -5.0$$

For $H_0 : \pi = 0.1$, the score test statistic is

$$z_S = (0 - 0.1) / \sqrt{0.1 \times 0.9 / 25} = -1.67$$

Statistical Inference for Binomial Parameters

Exact Small-Sample Inference

If n is **small**, it would be better to use binomial distribution directly rather than its normal approximation.

Statistical Inference for Binomial Parameters

Exact Small-Sample Inference

Clopper-Pearson interval : Assume that θ is a parameter that we are interested in. From observed data, how can we set confidence interval for θ ??

- 1 Set θ_0 as null hypothesis.
- 2 P-values exceed α in that null hypothesis?
- 3 If they do, θ_0 may be chosen properly.

The endpoints are the solutions in π_0 to the equations

$$\sum_{k=y}^n \binom{n}{k} \pi_0^k (1 - \pi_0)^{n-k} = \frac{\alpha}{2} \quad \sum_{k=0}^y \binom{n}{k} \pi_0^k (1 - \pi_0)^{n-k} = \frac{\alpha}{2}$$

$$\Rightarrow \left(\left[1 + \frac{n - y + 1}{y F_{2y, 2(n-y+1)}(\alpha/2)} \right]^{-1}, \left[1 + \frac{n - y}{(y + 1) F_{2(y+1), 2(n-y)}(\alpha/2)} \right]^{-1} \right)$$

Statistical Inference for Multinomial Parameters

Pearson Statistic for Testing a Specified Multinomial

$H_0 : \pi_j = \pi_{j0}, j = 1, \dots, c$ where $\sum_j \pi_{j0} = 1$

- $\mu_j := \mathbb{E}n_j = n\pi_{j0}$, *expected frequencies*.
- Pearson statistic : $X^2 = \sum_j \frac{(n_j - \mu_j)^2}{\mu_j}$
- Observed value : $X_o^2 \Rightarrow$ P-value : $P_{H_0}(X^2 \geq X_o^2)$
- If n is large enough, $X^2 \approx \chi_{c-1}^2$

Example : Testing Mendel's Theory

- Mendel's Prediction : 75% yellow, 25% green
- Experiment result : $n_1 = 6022, n_2 = 2001, n = 8023$
- $X^2 = 0.015$, P-value : 0.90, not contradict null hypothesis.

Statistical Inference for Multinomial Parameters

Pearson Statistic for Testing a Specified Multinomial

- Mendel performed several experiments of this type. In 1936, R.A. Fisher summarized Mendel's results.
- X_1^2, \dots, X_k^2 : Results of each experiment performed independently, with degree of freedom ν_1, \dots, ν_k
- $\sum_j X_j^2$ has a chi-squared distribution with $\text{df} = \sum_j \nu_j$.

Fisher obtained $P = 0.99996$, too good!

Goodness-of-fit tests can reveal not only when a fit is *inadequate*, but also when it is **better than random** fluctuations would have us expect.

Statistical Inference for Multinomial Parameters

Chi-squared Theoretical Justification

- ML estimate for $\pi_0 = (\pi_{10}, \dots, \pi_{c0})$ is $(n_1/n, \dots, n_{c-1}/n)$
- Denote i -th observation by $Y_i = (Y_{i1}, \dots, Y_{ic})$, $i = 1, \dots, n$.

$$\sum_j Y_{ij} = 1 \quad Y_{ij} Y_{ik} = 0 \quad \forall j \neq k$$

- $\mathbb{E} Y_{ij} = P(Y_{ij} = 1) = \pi_{j0} = \mathbb{E} Y_{ij}^2$
- $\mathbb{E} Y_i = \pi$ and $\text{cov}(Y_i) = \Sigma = (\sigma_{jk})$ where

$$\sigma_{jj} = \text{Var}(Y_{ij}) = \pi_{j0}(1 - \pi_{j0})$$

$$\sigma_{jk} = \text{cov}(Y_{ij}, Y_{ik}) = \mathbb{E} Y_{ij} Y_{ik} - \mathbb{E} Y_{ij} \mathbb{E} Y_{ik} = \pi_{j0} \pi_{k0}$$

$$\Sigma = \text{diag}(\pi_0) - \pi_0' \pi_0$$

Statistical Inference for Multinomial Parameters

Chi-squared Theoretical Justification

- Define $\hat{\pi} := \bar{Y} = \frac{1}{n} \sum_i Y_i$, by CLT,

$$\sqrt{n}(\hat{\pi} - \pi_0) \xrightarrow{d} \mathcal{N}(0, \Sigma)$$

- Multiply $A \in \mathbb{R}^{c \times c-1}$ defined by $A_{ii} = 1, A_{ij} = 0$

$$\sqrt{n}(\hat{\pi} - \pi_0)A \xrightarrow{d} \mathcal{N}(0, A'\Sigma A)$$

- $\hat{\pi} = (n_1/n, \dots, n_{c-1}/n)$, $\pi_0 = (\pi_{10}, \dots, \pi_{c-1,0})$

$$n(\hat{\pi} - \pi_0)' \Sigma_0^{-1} (\hat{\pi} - \pi_0) \xrightarrow{d} \chi_{c-1}^2$$

- Σ_0^{-1} has (j, k) th element $\frac{1}{\pi_{c0}}$ when $j \neq k$ and $(\frac{1}{\pi_{j0}} + \frac{1}{\pi_{c0}})$ when $j = k$

- $n(\hat{\pi} - \pi_0)' \Sigma_0^{-1} (\hat{\pi} - \pi_0) = \sum_j \frac{(n_j - \mu_j)^2}{\mu_j} =: X^2$

Contents

- 4 Statistical Inference for Multinomial Parameters**
 - Pearson Statistic for Testing a Specified Multinomial
 - Likelihood-Ratio Chi-Squared**
 - Testing with Estimated Expected Frequencies

Statistical Inference for Multinomial Parameters

Likelihood-Ratio Chi-Squared

Recall that under some regularity condition and under H_0 , the ratio of the likelihood is

$$\Lambda(X) = \frac{\sup_{\Theta_0} l(\beta)}{\sup_{\Theta_0 \cup \Theta_1} l(\beta)} \leq 1 \quad \text{and} \quad -2 \log \Lambda(X) \xrightarrow{d} \chi^2_\nu$$

The likelihood ratio statistic G^2 is

$$G^2 = -2 \log \frac{\prod_j (\pi_{j0})^{n_j}}{\prod_j (n_j/n)^{n_j}} = 2 \sum_j \log(n_j / n\pi_{j0})$$

The larger the value of G^2 , the greater the evidence against H_0 .

Statistical Inference for Multinomial Parameters

Likelihood-Ratio Chi-Squared

When H_0 holds, the Pearson X^2 and the likelihood ratio G^2 both have χ^2_{c-1} distribution.

$$X^2 - G^2 \xrightarrow{P} 0$$

When H_0 is false, they need not take similar values.

Statistical Inference for Multinomial Parameters

Testing with Estimated Expected Frequencies

Pearson's X^2 compares a sample distribution to a hypothetical one $\{\pi_{j0}\}$.

$$X^2 = \sum_{j=1}^c \frac{(n_j - \mu_j)^2}{\mu_j}$$

In some cases, $\pi_{j0} = \pi_{j0}(\theta)$, $\theta \in \Theta \subset \mathbb{R}^p$

→ cannot get $X^2 \Rightarrow$ replace μ_j by $\hat{\mu}_j$

The distribution of X^2 is a chi-squared distribution with $df = (c - 1) - p$.

Statistical Inference for Multinomial Parameters

Testing with Estimated Expected Frequencies

TABLE 1.1 Primary and Secondary Pneumonia Infections in Calves

Primary Infection	Secondary Infection ^a	
	Yes	No
Yes	30 (38.1)	63 (39.0)
No	0 (—)	63 (78.9)

$$H_0 : P(\text{1st infection}) = P(\text{2nd infection} | \text{1st infection})$$

$$\Leftrightarrow H_0 : \pi_{11} + \pi_{12} = \pi_{11} / (\pi_{11} + \pi_{12})$$

Under H_0 , $\pi := \pi_{11} + \pi_{12}$, $\pi_{11} = \pi^2$, $\pi_{12} = \pi - \pi^2$, and $\pi_{22} = 1 - \pi$

$$\hat{\pi} = \arg \max l(\pi) = (\pi^2)^{n_{11}} (\pi - \pi^2)^{n_{12}} (1 - \pi)^{n_{22}}$$

$$\hat{\pi} = (2n_{11} + n_{12}) / (2n_{11} + 2n_{12} + n_{22}) = 0.494 \Rightarrow X^2 = 19.7 \text{ (df=1)}$$

$P = 0.00001$: Strong evidence against H_0
